This paper describes Serial Storage Architecture (SSA), a definition and general specification of a high-performance serial link for the attachment of input/output devices. An overview is given of the architecture itself, followed by a general description of the hardware implementation of a dual-port SSA node on a single chip.

Introduction

Serial Storage Architecture (SSA) defines a high-performance serial link for the attachment of input/output devices. It has been optimized for storage applications such as hard disk drives, host adapter cards, and array controllers. SSA has many advantages over existing parallel interfaces such as the Small Computer Systems Interface (SCSI-2). It uses compact cables and connectors, and it has better performance, connectivity, and reliability. However, to facilitate migration, SSA retains much of the SCSI-2 logical protocol.

Current SSA implementations such as the IBM 7133 Disk Subsystem [1] provide a peak data rate of 20 MB/s in each direction. However, a typical loop configuration with one host adapter can provide a total sustained bandwidth of up to 73 MB/s, and higher speeds are becoming available. The physical medium is usually a copper cable up to 20 meters long, but fiber optics can also be used for longer distances.

This paper describes the link architecture and its implementation in a single CMOS chip.

Why serial?

Serial links offer many advantages over traditional parallel interfaces:

- **Compact cables and connectors**—This is becoming increasingly important with the trend to small-form-factor devices, e.g., 3.5-in. and 2.5-in. hard disk drives.
- **Improved connectivity**—A single host interface can attach many devices. The devices can also be shared among several host computers.
- **Higher performance**—A serial interface can provide full-duplex communications at little extra cost. Frame multiplexing allows the interface to be shared efficiently among several concurrent operations.
- **Higher reliability**—Error detection is improved by using a cyclic redundancy check (CRC) rather than a simple bus parity check. Point-to-point cables allow faults to be isolated more easily than in a multidrop bus. Devices can readily be dual-ported to provide alternate paths and allow continuous operation in the event of a fault. Individual devices can be "hot-swapped" for concurrent maintenance.

Architecture overview

SSA is defined in three layers:

- **SSA-PII** [2] defines the electrical specifications, cables, and connectors.
- **SSA-TLI** [3] is a general-purpose transport layer. It defines the transmission protocol, configuration, and error recovery.
- **SSA-SIP** [4] is a mapping of the SCSI-2 queuing model, command set, status, and sense bytes.

Transport layer (SSA-TLI)

- **Nodes**

An SSA node is an addressable unit such as a host adapter card, a switch, or a hard disk drive. In some cases a
