

Chemical Bonding Lab

Chemical compounds are combinations of atoms held together by chemical bonds. There are two basic types of chemical bonds—ionic and covalent. Ionic bonds result when one or more electrons from one atom (or group of atoms) are transferred to another atom. Positive and negative ions are created through the transfer of electrons, and they are held together by electrostatic attraction (opposites attract). In covalent compounds, no electrons are transferred; instead, electrons are shared by the bonded atoms.

The physical properties of a substance, such as melting point (the temperature a substance turns into a liquid), solubility (whether or not a substance will dissolve), and conductivity (whether a substance lets a current pass through it), can be used to predict the type of bond that binds the atoms of the compound together. In this experiment, you will test six compounds to determine these properties, compare your data, and draw conclusions about which bonds possess which properties.

Pre-Lab:

- Describe what types of elements create ionic bonds.
- Describe what type of elements make covalent bonds.
- Draw Lewis structures and predict the formulas for the following compounds:
 - Calcium chloride
 - Sodium Chloride
 - Potassium Iodide
- Look up the chemical formulas for the following compounds and list them below:
Aspirin, Acetaminophen, Sucrose
