Title: Plot the characteristic curve of Phototransistor

Objectives:

- Explore the working principle of phototransistor
- Study signal conditioning method of phototransistor
- Plot and investigate the characteristic curve of phototransistor

Theory:

A phototransistor is a device that converts light energy into electric energy. A phototransistor is made of a bipolar semiconductor and focuses the energy that is passed through it. Photons (light particles) activate phototransistors and are used in virtually all electronic devices that depend on light in some way. Although ordinary transistors exhibit the photosensitive effects if they are exposed to light, the structure of the phototransistor is specifically optimized for photo applications. The photo transistor has much larger base and collector areas than would be used for a normal transistor.

Phototransistors are generally encased in an opaque or clear container in order to enhance light as it travels through it and allow the light to reach the phototransistor's sensitive parts. The light enters the base region of the phototransistor where it causes electron-hole pairs to be generated. This mainly occurs in the reverse biased base-collector junction. The hole-electron pairs move under the influence of the electric field and provide the base current, causing electrons to be injected into the emitter.

Photo transistors are operated in their active region, although the base connection is left open circuit or disconnected because it is not required. The base of the photo transistor would only be used to bias the transistor so that additional collector current was flowing and this would mask any current flowing as a result of the photo-action. For operation the bias conditions are quite simple. The collector of an n-p-n transistor is made positive with respect to the emitter or negative for a p-n-p transistor.
