

using the emitter bypass. The circuit becomes more nonlinear — that is, there is less opportunity for the operating point of the amplifier to shift, less chance for collector-current runaway. The gain of the stage is reduced, just as it is in vacuum-tube circuits.

Fig. 30.  $R_1$  and  $C_1$  act as a voltage divider across the battery.

However, the stage becomes more linear in its operation — there is less distortion. The frequency response of the amplifier becomes wider. And, finally, the input impedance increases.

Fig. 31. The emitter resistor,  $R_1$ , is bypassed by capacitor  $C_1$ . If  $C_1$  is an electrolytic, its polarity must be the same as that of the power source.

The amount of degeneration obtained depends upon the voltage drop across the emitter resistor. Remember — the voltage across the emitter resistor opposes the forward bias of the transistor input circuit. The larger the resistor, the greater this voltage drop will be, hence the amount of degenerative feedback will be greater.

Fig. 32. When using an n-p-n unit as place of p-n-p, not only must the battery lead be reversed, but the emitter bypass (if an electrolytic) must also have its lead changed.

Fig. 33. The photo shows typical resistors used in transistor circuits. These are very small compared to the units you will find in vacuum-tube circuits.
