Poljakov, 1972 Neuron Structure-function Correspondence as Revealed by Biological Scaling Theory Paheli Desai-Chowdhry, 2023

Neurons are connected by complex branching processes that collectively process information for organisms to respond to their environment Classifying neurons according to differences in structure or function is a fundamental piece of neuroscience Here by constructing new biophysical theory and testing against our empirical measures of branching structure we establish a correspondence between neuron structure and function as mediated by principles such as time or power minimization for information processing as well as spatial constraints for forming connections Based on these principles we use Lagrange multipliers to predict scaling ratios for axon and dendrite sizes across branching levels We test our predictions for radius scale factors against those extracted from images measured for species that range from insects to whales Notably our findings reveal that the branching of axons and peripheral nervous system neurons is mainly determined by time minimization while dendritic branching is mainly determined by power minimization Further comparison of different dendritic cell types reveals that Purkinje cell dendrite branching is constrained by material costs while motoneuron dendrite branching is constrained by conduction time delay We extend this model to incorporate asymmetric branching where there are multiple different paths from the soma to the synapses and thus multiple interpretations of conduction time delay one considers the optimal path and the other considers the sum of all possible paths leading to different predictions We find that the data for motoneurons show a distinction between the asymmetric and symmetric branching junctions corresponding to predictions using different interpretations of the time delay constraint Moreover the more asymmetric branching junctions are localized near the synapses indicating that different functional principles affect the structure at different regions of the cell Finally we use machine learning methods to classify cell types using functionally relevant structural parameters derived from our model Incorporating branching level as a feature in classification in addition to parameters related to information flow improves performance across methods suggesting that information flow drives localized differences in morphology Future directions of this work include estimating specific parameters related to functional tradeoffs and myelination using numerical optimization and analyzing changes across stages of development *The Generalized Vertebrate Neuron* David Bodian, 1962 **Neuron Structure Analysis: Structure**

**Reconstruction and Dynamic Analysis** Ann-Shyn Chiang, Yu-Tai Ching, Ping-Chang Lee, 2012 *Use of Data Assimilation to Determine Features of Neuron Structure and Connectivity* Michael James Eldridge, 2016 Neurons and the synaptic connections between them underlie the computational power of the brain We present numerical models of neural behavior and show how to tune these models based on experimental evidence Though the basic principles behind the creation and propagation of action potentials are understood it is experimentally feasible to measure only a small number of the quantities that go into our models substantially increasing the difficulty of making accurate predictions Additionally because biologically motivated models are very often nonlinear we will focus on tools and techniques which do not require linearity We present novel methods of using time series of measurements to determine the features of nonlinear systems and predict their future behavior We show how time delayed coordinates can substitute for additional measurements and provide us with a better estimation of the state and parameters of the underlying system A general expression for our objective function as a path integral is derived from probabilistic considerations and methods for evaluating the expression are discussed We demonstrate how the techniques developed can be used to determine properties of a biophysical system from a realistic set of limited measurements We examine experimental electrophysiological recordings of zebra finch neurons and use them to hone the predictive powers of our models for single cells Then moving beyond the single cell level we demonstrate how our approach can be used to determine changes in network connectivity due to synaptic plasticity in ways that direct experiment cannot
