

Genes Regulation in Prokaryotes - Top and Left Operons

1. **Left Operon** (lac operon): Operon structure for lactose metabolism. It consists of a promoter, an operator, and a structural gene. The promoter is a region of DNA where RNA polymerase binds to initiate transcription. The operator is a region of DNA where a repressor protein binds to prevent transcription. The structural gene codes for the enzymes involved in lactose metabolism.

2. **Top Operon** (trp operon): Operon structure for tryptophan metabolism. It consists of a promoter, an operator, and a structural gene. The promoter is a region of DNA where RNA polymerase binds to initiate transcription. The operator is a region of DNA where a repressor protein binds to prevent transcription. The structural gene codes for the enzymes involved in tryptophan metabolism.

Diagram 1: Diagram of the lac operon. It shows the promoter, operator, and structural gene. The promoter is a region of DNA where RNA polymerase binds to initiate transcription. The operator is a region of DNA where a repressor protein binds to prevent transcription. The structural gene codes for the enzymes involved in lactose metabolism.

The Lac Operon Benno Müller-Hill,

The Life-cycle of Operons ,2007 Operons are a major feature of all prokaryotic genomes but how and why operon structures vary is not well understood To elucidate the life cycle of operons we compared gene order between *Escherichia coli* K12 and its relatives and identified the recently formed and destroyed operons in *E. coli* This allowed us to determine how operons form how they become closely spaced and how they die Our findings suggest that operon evolution may be driven by selection on gene expression patterns First both operon creation and operon destruction lead to large changes in gene expression patterns For example the removal of *lysA* and *ruvA* from ancestral operons that contained essential genes allowed their expression to respond to lysine levels and DNA damage respectively Second some operons have undergone accelerated evolution with multiple new genes being added during a brief period Third although genes within operons are usually closely spaced because of a neutral bias toward deletion and because of selection against large overlaps genes in highly expressed operons tend to be widely spaced because of regulatory fine tuning by intervening sequences Although operon evolution may be adaptive it need not be optimal new operons often comprise functionally unrelated genes that were already in proximity before the operon formed

The lac Operon Benno Müller-Hill,2011-05-12 No detailed description available for The lac Operon

Operon Formation is Driven by Co-Regulation and Not by Horizontal Gene Transfer ,2005 Although operons are often subject to horizontal gene transfer HGT non HGT genes are particularly likely to be in operons To resolve this apparent discrepancy and to determine whether HGT is involved in operon formation we

examined the evolutionary history of the genes and operons in Escherichia coli K12. We show that genes that have homologs in distantly related bacteria but not in close relatives of E. coli indicate HGT. New operons form at about the same rates as native genes. Furthermore, genes in new operons are no more likely than other genes to have phylogenetic trees that are inconsistent with the species tree. In contrast, essential genes and ubiquitous genes without paralogs, genes believed to undergo HGT rarely form new operons. We conclude that HGT is not associated with operon formation but instead promotes the prevalence of pre-existing operons. To explain operon formation, we propose that new operons reduce the amount of regulatory information required to specify optimal expression patterns. Consistent with this hypothesis, operons have greater amounts of conserved regulatory sequences than do individually transcribed genes.
