

Retractile Mesenteritis Involving the Colon: Pathologic and Radiologic Correlation (Case Report)

Retractile mesenteritis is a disease of the mesentery that results in fat necrosis, chronic inflammation, and fibrosis [1]. It is characterized clinically by abdominal pain, diarrhea, and weight loss [2]. It involves the mesentery of both small intestine and colon and can occur independently or in association with other disorders predisposing to fibrosis, such as carcinoid tumor and retroperitoneal fibrosis [3].

The etiology of this disorder is unknown. Of various potential causes, ischemia of the mesentery has been favored, but evidence for this is meager [4]. We studied a patient with retractile mesenteritis involving the colon using colonoscopy, CT, angiography, and barium enema. The results of these studies and the examination of the resected specimen suggest that retractile mesenteritis is the end result of a complicated pathologic process that begins with angiomatoid proliferation, localized intravascular coagulation, ischemia, and necrosis and progresses to fibrosis. Ischemia, which represents only one stage in the process, may be responsible for the colonic change that occurs in the disease.

Case Report

A 58-year-old man was admitted with a 4-month history of abdominal pain, diarrhea, and weight loss. Physical examination revealed a tender mass in the left abdomen. On colonoscopy the rectum was unremarkable. The mucosa of the sigmoid and descending portions of the colon were engorged, edematous, and heaped up, but no ulceration was seen. The histology of a biopsy specimen was normal.

Barium enema examination demonstrated rigidity of the sigmoid and descending colon with thickening and distortion of rugal folds on the mesenteric border (Fig. 1). In addition, there was a smooth extrinsic impression on the medial wall of the descending colon presumably caused by thickened mesentery. The appearance of the remainder of the colon was normal. CT revealed narrowing of the lumen of the involved portions of the colon with marked colonic wall thickening. There was a lobulated, low-density mass in the mesentery suggesting fatty infiltration (Fig. 2). An inferior mesenteric arteriogram showed that the terminal arterial branches were diminished in number and constricted, indicating diminished perfusion of the mesentery and colonic wall (Fig. 3). Venous drainage was delayed. A second barium

enema 2 weeks later revealed submucosal edema of the sigmoid and descending colon with "thumbprinting."

Because of lack of clinical improvement and a tender mass in the left lower abdomen, a decision was made to operate to establish a diagnosis. The descending and sigmoid portions of the colon were resected with the adjacent mesentery and pericolic fat. At surgery, the thickened, lobulated mesentery was found to form a firm, fatty mass with red-brownish discoloration (Fig. 4).

The mucosa of the resected colon contained several areas of pseudomembrane formation but was otherwise intact. Microscopic examination showed extensive mesenteric fat necrosis characterized by xanthogranulomatosis and fibrosis, focal mucosal ulceration, pseudomembrane formation, and submucosal edema. There was a remarkable degree of colonic wall thickening. The most striking finding was angiomatoid proliferation of vessels in the mesenteric adipose tissue, submucosa, and muscular wall of the colon (Fig. 5). Fibrinoid necrosis and microthrombi were common in these small vessels indicating active intravascular coagulation (Fig. 5). The large arteries showed only minimal intimal thickening.

The patient made an uneventful postoperative recovery and was discharged with a diverting colostomy and Hartmann's pouch.

Discussion

The pathology of retractile mesenteritis is thought to be mesenteric panniculitis with subsequent fibrosis [5]. Various terms have been used to describe these predominant features: primary liposclerosis, mesenteric lipomatosis, mesenteric panniculitis, chronic fibrosing mesenteritis, and mesenteric lipofibromatosis.

Previously described radiologic features of retractile mesenteritis [3, 6, 7] include narrowing and rigidity of a segment of colon with thumbprinting and mesenteric mass. Adjacent intestinal loops may be displaced or separated by thickened mesentery. Mesenteric fibrosis may cause kinking and angulation of the intestine. The prominent CT finding is a low-density mass with linear strands in the mesentery. Irregularity of the mesenteric arterial branches and venous congestion have been mentioned as angiographic manifestations. Most of these findings were seen in our patient.
