*Restoration of the Endodontically Treated Tooth* Herbert T. Shillingburg, James C. Kessler, 1982      **Restoration of Endodontically Treated Teeth** Dr KANHAIYA LAL GUPTA, 2011-03 Endodontic treatment saves the tooth from extraction but only adequate restoration will reinstate it as a long term functioning member of the mouth The restoration of a tooth by root canal treatment is of limited value unless the crown of tooth is satisfactorily restored The manner in which a root canal filled tooth is restored is therefore considerable importance The restoration of endodontically treated tooth is complicated by the fact that much or all of the coronal tooth structure which normally would be used in the retention of the restoration has been destroyed by caries previous restorations trauma and the endodontic access preparation itself The endodontically treated tooth is a unique subset of teeth requiring restoration because of several factors such as dehydrated dentin decreased structural integrity and impaired neurosensory feed back mechanism when compared to a vital tooth However the treatment goal must be based upon a multitude of factors specific for each patient so that the strategic architectural aspects that have greatest impact on the ultimate strength of the pulpless tooth can be restored reinforced

**Ability Of Different Posts To Reinforce Endodontically Treated Teeth**  
 Abdulrahman Fadag,Maged Negm,Geraldin Mohamed Ahmed,2015-11-18 Restoration of an endodontically treated tooth because of the significant loss of tooth structure often requires additional support from the root canal by means of a post and core restoration However post may generate stresses which lead to vertical root fracture and loss of the tooth Since post design material used and the post space preparation has a significant influence on vertical fracture prevalence broad investigation is in progress to find out the optimum procedure Esthetic functional and structural rehabilitation of a pulpless tooth are critically important to ensure a successful restorative outcome In cases where most of the coronal portion is lost a common method to restore such teeth is the use of a post and core onto which a full crown is cemented The post functions primarily to aid the retention of the restoration and to protect the tooth by dissipating or distributing forces along the tooth On the contrary the tooth is weakened if dentin is sacrificed to place a large diameter dowel The main purpose of this study was to evaluate the ability of different types of posts to reinforce endodontically treated teeth
