

The use of molecular barcodes in Anchored Multiplex PCR (AMP™) chemistry

How molecular barcodes differ from sample indexes

Sample barcoding, also called sample indexing, is a common approach to labeling samples for multiplex sequencing and analysis. All nucleic acids in a sample are labeled with the same sequence tag, and the resulting library is pooled and sequenced in parallel in a single run. Then, during analysis, the sample-specific indexes enable the software to separate the multiplexed sequence data into sample-specific data sets (Figure 1A).

Molecular barcoding differs from sample indexing, in that each molecule in a sample is labeled with a unique sequence prior to PCR amplification. With each nucleic acid in the starting material tagged with a unique molecular barcode (MBC), sequence analysis software can filter out duplicate reads and PCR errors to report more accurate unique reads which in turn results in more accurate variant determination (Figures 1 and 2).

Figure 1. Sample indexes differ from molecular barcodes (MBCs). (A) Each sample is labeled with a unique sample index. The sample libraries are then sequenced, and analysis software bins the data based on the index in each sample. (B) Each cDNA or DNA molecule in a sample has the same sample index, but a unique MBC ligated before amplification. (C) After amplification and sequencing, the software generates consensus sequences based on MBCs, which helps remove PCR errors (red lines) or amplification bias.
