and iron loading. Importantly as the disease progresses there is concurrent loss of liver function. Furthermore postoperative liver function insufficiency is an important concern when planning surgical treatment of the liver because it is associated with both morbidity and mortality. Liver function can also be hampered due to drug induced injuries an important aspect to consider in drug development. Currently an invasive liver needle biopsy is required to determine the aetiology and to stage or grade the pathophysiological manifestations. There are important limitations with the biopsy which include risk of serious complications mortality morbidity inter and intra observer variability sampling error and sampling variability. Clearly it would be beneficial to be able investigate the pathophysiological manifestations accurately non invasively and on regional level. Current available laboratory liver function blood panels are typically insufficient and often only indicate damage at a late stage. Thus it would be beneficial to have access to biomarkers that are both sensitive and responds to early changes in liver function in both clinical settings and for the pharmaceutical industry and regulatory agencies. The main aim of this thesis was to develop and evaluate methods that can be used for a non invasive liver biopsy using magnetic resonance MR. We also aimed to develop sensitive methods for measure liver function based on gadoxetate enhanced MR imaging MRI. The presented work is primarily based on a prospective study on c 100 patients suffering from chronic liver disease of varying aetiologies recruited due to elevated liver enzyme levels without clear signs of decompensated cirrhosis. Our results show that the commonly used liver fat cut off for diagnosing steatosis should be lowered from 5% to 3% when using MR proton density fat fraction PDFFF. We also show that MR elastography MRE is superior in staging fibrosis. Finally we presented a framework for quantifying liver function based on gadoxetate enhanced MRI. The method is based on clinical images and a clinical approved contrast agent gadoxetate. The framework consists of state of the art image reconstruction and correction methods a mathematical model and a precise model parametrization method. The model was developed and validated on healthy subjects. Thereafter the model was found applicable on the chronic liver disease cohort as well as validated using gadoxetate levels in biopsy samples and blood samples. The liver function parameters correlated with clinical markers for liver function and liver fibrosis used as a surrogate marker for liver function. In summary it should be possible to perform a non invasive liver biopsy using MRI PDFFF for liver fat and iron loading MRE for liver fibrosis and possibly also inflammation and measure liver function using the presented framework for analysing gadoxetate enhanced MRI. With the exception of an MRE transducer no additional hardware is required on the MR scanner. The liver function method is likely to be useful both in a clinical setting and in pharmaceutical trials.
