

## Photosynthesis

## KEY CONCEPTS

- 8.1** Photosynthesis converts light energy to the chemical energy of food.
- 8.2** The light reactions convert solar energy to the chemical energy of ATP and NADPH.
- 8.3** The Calvin cycle uses the chemical energy of ATP and NADPH to reduce  $\text{CO}_2$  to sugar.

**A. Figure 8.1** How does sunlight help build the trunk, branches, and leaves of this broadleaf tree?

## The Process That Feeds the Biosphere

Life on Earth is solar powered. The chloroplasts in plants and other photosynthetic organisms capture light energy that has traveled 150 million km from the sun and convert it to chemical energy that is stored in sugar and other organic molecules. This conversion process is called **photosynthesis**. Let's begin by placing photosynthesis in its ecological context.

Photosynthesis nourishes almost the entire living world directly or indirectly. An organism acquires the organic compounds it uses for energy and carbon skeletons by one of two major modes: autotrophic nutrition or heterotrophic nutrition. **Autotrophs** are "self-feeders" (*auto-* means "self," and *trophos* means "feeder"); they sustain themselves without eating anything derived from other living beings. Autotrophs produce their organic molecules from  $\text{CO}_2$  and other inorganic raw materials obtained from the environment. They are the ultimate sources of organic compounds for all nonautotrophic

organisms, and for this reason, biologists refer to autotrophs as the *producers* of the biosphere.

Almost all plants are autotrophic; the only nutrients they require are water and minerals from the soil and carbon dioxide from the air. Specifically, plants are *photoautotrophs*, organisms that use light as a source of energy to synthesize organic substances (Figure 8.1). Photosynthesis also occurs in algae, certain other unicellular eukaryotes, and some prokaryotes.

**Heterotrophs** are unable to make their own food; they live on compounds produced by other organisms (*hetero-* means "other"). Heterotrophs are the biosphere's *consumers*. This "other-feeding" is most obvious when an animal eats plants or other animals, but heterotrophic nutrition may be more subtle. Some heterotrophs decompose and feed on the remains of dead organisms and organic litter such as feces and fallen leaves; these types of organisms are known as decomposers. Most fungi and many types of prokaryotes get their nourishment this way. Almost all heterotrophs, including humans, are completely dependent, either directly or indirectly, on photoautotrophs for food—and also for oxygen, a by-product of photosynthesis.
