

Keystone Species

Saguaro Cactus

What is a keystone species?

A keystone species is a species that has a disproportionately large effect on its environment relative to its abundance. The concept was developed by ecologist Robert Paine in the 1960s, based on his studies of intertidal ecosystems. Paine found that the removal of a single species, the starfish *Pisaster ochaceus*, led to a dramatic change in the community structure of the rocky shore.

Keystone species can be found in a wide variety of ecosystems, from marine environments to terrestrial habitats. They often play a role in maintaining the balance of an ecosystem, and their removal can lead to a collapse of the system. Examples of keystone species include wolves in Yellowstone National Park, beavers in wetland ecosystems, and elephants in savanna habitats.

Why is the Saguaro a keystone species?

The Saguaro cactus is a keystone species in the Sonoran Desert. It provides food and shelter for a wide variety of animals, including birds, mammals, and reptiles. The cactus also plays a role in the desert's water cycle, storing water in its thick stems and releasing it slowly over time. Without the Saguaro, the desert ecosystem would be fundamentally altered.
