Abstract The application of deformation theory in section analysis of reinforced concrete members is based on the use of ultimate values of concrete compressive strains at the time of failure. These strains may be determined analytically by examining the bearing capacity function at the extremum. In such a study, it is usually assumed that the tensile reinforcement reaches the yield point and the stress in it is constant. When using high-strength reinforcement with conditional yield strength, the stress in the reinforcement at the moment of failure is not a constant value. This is also characteristic of over-reinforced members, in which at the moment of destruction stress in tensile reinforcement is less than its yield stress. For such a case, an analytical criterion for determining the ultimate compressive strain of concrete of reinforced concrete members is proposed. This criterion, together with the extreme concrete strength criterion, which is used for common reinforced concrete members, may be used as the basis of the methodology for calculating the strength of reinforced concrete structures. The ultimate compressive strains of concrete are determined by using the derived criterion for a range of concrete classes that match coefficient k from 1 to 5. Simple analytical dependencies for section analysis of reinforced concrete members with high-strength reinforcement are obtained on the basis of ultimate compressive strains of concrete. The application of the developed method is considered using examples.

Keywords Reinforced Concrete Member, Ultimate Concrete Strain, Section Analysis

1. Introduction

At present, the analysis of the section of reinforced concrete members is based on the deformation model. Determination of the design (ultimate) values of concrete compressive strain in the composition of the reinforced concrete member is carried out by different approaches. One of them is characterized by the application of ultimate values of concrete strain in the most compressed fiber determined experimentally [1–6]. According to the other approach, the introduced concept of the extreme strength criterion of a reinforced concrete member $\partial M / \partial \varepsilon_{cm} = 0$ is used. The ultimate values of concrete strain in the composition of flexural reinforced concrete members are determined analytically by studying the function $M_{du} = f(\varepsilon_{cm})$ on the extremum, where ε_{cm} is the strain of concrete in the most compressed cross-sectional fiber of reinforced concrete member [7–10]. Analytical approaches to determining ultimate compressive strain based on the energy balance method [11–12] and others [13–14] are known.

The application of the extreme criterion is possible for normally reinforced concrete members, namely those in
