Repeated Manual Release in a Young Plantation Philip M. McDonald, 1994 Douglas fir seedlings on the Arcata Resource Area Bureau of Land Management U S Department of the Interior in central coastal California were released by chain sawing and grubbing competing vegetation around them at different frequencies 0 2 and 3 grubblings over a 5 year period. After 5 years average Douglas fir stem diameter measured at 12 inches above mean groundline of seedlings grubbed at ages 1 2 and 5 was 0.91 inches and of seedlings grubbed after the first and fifth growing season was 0.95 inches. Both were significantly larger than counterparts in the control 0.57 inches. Tanoak the most competitive species constituted 84 percent of total plant cover in the control after 5 years but only 25 percent on treated plots. Combined shrubs varied little between the untreated control and treated plots and averaged about 7 percent of total foliar cover. Grasses were not present in the control and only for the fifth year in treated plots. The most abundant forb a hedge nettle increased greatly in density in both control and treated plots. These relationships and others denoted in the paper yield valuable ecological information on species and community dynamics in both a natural and treated environment.
